*Twisted endoscopy in the framework of Adams-Barbasch-Vogan*

Endoscopic transfer was originally expressed in terms of identities between distributions defined from either orbital integrals or characters. In the early 1990's Adams, Barbasch and Vogan proved endoscopic identities for real groups which were defined using sheaf theory. We shall describe how the theory of twisted endoscopy, established by Kottwitz and Shelstad, may be integrated into the sheaf-theoretic framework.
